University of Tübingen Seminar für Sprachwissenschaft

Winter Semester 2020/21

Natural, artificial, formal languages

- · Some languages in our list are natural languages
- · In contrast some are designed, they are artificial
- · Formal languages are those that we can study formally
 - we can analyze them in principled ways
 - provably answers the questions about them
- All languages in our list can be studied as formal languages (to some extent)

Ç. Çöltekin, SfS / University of Tübingen

Winter Semester 2020/21 2 / 35

Ç. Çöltekin, SfS / University of Tübingen

Winter Semester 2020/21 3 / 35

Formal grammar

A formal *grammar* is a finite specification of a (formal)

- Since we consider languages as sets of strings, for a finite language, we can (conceivably) list all strings
- · How to define an infinite language?
- Is the definition $\{b\alpha,b\alpha\alpha,b\alpha\alpha\alpha,b\alpha\alpha\alpha\alpha,\ldots\}$ 'formal enough'?
- Using regular expressions, we can define it as $b\alpha\alpha^*$
- But we will introduce a more general method for defining languages soon
- · Are natural languages infinite?

Ç. Çöltekin, SfS / University of Tübingen

Operations on languages

Since we define languages as sets, all set operations are applicable to languages. If L1 and L2 are languages,

- Intersection: $L_1 \cap L_2$
- Union: $L_1 \cup L_2$
- Difference: L₁ − L₂
- Complement: $\Sigma^* L_1$
- $\bullet \ \ Concatenation : \ L_1L_2 = \{xy|x \in L_1 and y \in L_2\}$

What is a language?

- English, German, Chinese
- Latin, Coptic, Sanskrit, Sumerian
- Proto-Germanic, Proto-Uralic, Proto-Dravidian
- Sign languages
- Esperanto
- Traffic signs, computer icons, emoticons
- Chemical formulas
- Arithmetic expressions
- Python, Java, C++
- XML, JSON, HTML, YAML
- HTTP, TCP, UDP,
- · The set of strings $\{ba, baa, baaa, baaaa, \ldots\}$

According to Jurafsky and Martin (2009), the last set of strings form the 'sheep language

Languages as sets of strings

We define a formal language as a set of finite-length string over an alphabet.

 $\bullet\,$ The sheep language from the first slide was represented as

{ba, baa, baaa, baaaa....}

The alphabet of a language is the set of "symbols" in the language, conventionally denoted as $\boldsymbol{\Sigma}.$

- For the sheep language, $\Sigma = \{a, b\}$
- What is the alphabet for English syntax?

Formal languages

Some definitions

Alphabet is the set of 'atomic' symbols in the language String is a sequence of symbols from the alphabet, For example, 101100 is a string over alphabet $\Sigma = \{0,1\}$

- Concatenation: if x = 10 and y = 11000101, their concatenation xy = 1011000101
- \bullet We represent the empty string with ε (some books use λ)
- The notation x^* indicates zero or more concatenation of string x with itself, e.g., ϵ , 01, 010101 (the operation is called Kleene star)
- The notation x^+ is a shorthand for xx^*
- xⁿ means exactly n repetition of string x
- Σ^* is all possible strings that can be defined over alphabet Σ

Sentence of a language is a string that is in the language (confusingly the term word is also common)

Ç. Çöltekin, SfS / University o

Introduction

Three different view on formal languages

- In formal language theory, a language is studied for itself. Languages are simply set of strings, we do not attach 'meaning' to them. The questions of interests are abstract. For example, 'how to find the intersection of two languages for which we have grammars?'
- In computer science, we want to analyze the structure (of, e.g., a computer program) to get some information, or 'meaning'. The most common area is compiler construction, but almost any syntactic analysis task is supported by formal definitions of the respective languages.
- In (computational) linguistics, the aim is to analyze sentences (syntax), and associate them with their meanings (semantics). Formal languages provide a way to study a seemingly chaotic object, natural language, in a principled way.

Grammars: how to describe a language?

- In daily use, a 'grammar' is a book, it defines a language in
- But we are interested in more formal grammars
- The challenge is describing a possibly infinite set with a finite specification
- We already see that it was possible (e.g., regular expressions)
- Another possible way would be writing a computer program that determines if the given string is in the
- However, we want more general descriptions: grammars that can describe any 'describable' language in a concise and easy to study formalism

Aside: can any language be described by a finite description?

· A phrase structure grammar is a generative device

- If a given string can be generated by the grammar, the string is in the language
- The grammar generates all and the only strings that are valid in the language
- · A phrase structure grammar has the following components
 - Σ A set of terminal symbols

Phrase structure grammars

- N A set of non-terminal symbols
- $S \in \mathbb{N}$ A special non-terminal, called the start symbol
 - R A set of rewrite rules or production rules of the form:

 $\alpha \ \to \ \beta$

which means that the sequence α can be rewritten as β (both α and β are sequences of terminal and non-terminal symbols)

Phrase structure grammars

Some conventions

- We use uppercase letters (sometimes capitalized words) for non-terminal symbols: A, B, C, NP, End
- · We use lowercase letters (sometimes lowercase words) for terminals: a, b, c, cat, dog
- We use Greek letters letters for sentential forms, (sequences of terminal and non-terminal symbols): α , β , γ
- For sequences of terminal symbols (strings) we use lowercase letters from the end of the alphabet: u, v, w, x, y,

Ç. Çöltekin, SfS / University of Tübingen

Generating sentences from a PSG

- 1. Start with the symbol S as the first sentential form
- 2. Pick a rule with matching the part of the current sentential form
- 3. Apply the rewrite (production) rule
- 4. Repeat 2 and 3, until there are no non-terminals left
- · Exhaustively exploring all possible productions 'enumerates' all sentences of the language described by the grammar

• The above procedure (generating all sentences from a generative grammar) gives us a possible way to do

If it does not come out, it is not in the language: parsing

 Enumerate all sentences from the grammar If the string we are interested comes out, it is in the

failed (we'll get back to this point soon) · We will also see later that this is in fact the idea behing

language: parsing is successful

Ç. Çöltekin, SfS / University of Tübingen

Generation to parsing

parsing:

top-down parsers

Winter Semester 2020/21 11 / 35

Phrase structure grammars

A very simple example - the sheep language

A grammar				
$1.\mathrm{S}\rightarrow\mathrm{B}\mathrm{A}$				
2. B \rightarrow b				
3. $A \rightarrow a A$				
4. A → a				

Quick exercise: try to define a different grammar for the same language.

An example deriva	tion	
Sentential form	rule	notes
S		start symbol
BA	$S \to BA$	rule 1
bA	$B \to b$	rule 2
baA	$A \to a A$	rule 3
baaA	$A \to a A$	rule 3
baaa	$A \to a$	rule 4

Ç. Çöltekin, SfS / University of Tübingen

Ç. Çöltekin, SfS / University of Tübingen

Winter Semester 2020/21 13 / 35

Phrase structure grammars

Another example: the goat language (a dialect of sheep language) 1

The grammar

- 1. $S \rightarrow Begin B$ A End
- $2. \ B \ \rightarrow \ b$
- 3. $A \rightarrow a$
- $4. A \rightarrow a A$
- 5. a A End \rightarrow a ′ a
- 6. Begin b a $\,\rightarrow\,$ b b a
- 7. Begin b b \rightarrow b b
- A few exercises:
 - Describe the language
 - Derive the string bbaaa'a
 - Is the string baa'a in the language?
 - Can you write a simpler grammar for this language?

Phrase structure grammars A few notes

- · The phrase structure grammars are not the only method for defining languages (sets)
- · However, all known methods are either equivalent to, or less powerful than phrase structure grammars
- The formalism we sketched is general: any set (language) that can be generated by a computer program can be defined by a phrase structure grammar

1 Some claim that the grammar is just the same, but goats use the word m instead of the word b.

Winter Semester 2020 / 21 15 / 35

Type 0 Unrestricted phrase structure grammars

Type 2.1 Mildly-context sensitive grammars

Type 1 Context-sensitive or monotonic grammars

• We introduce one restriction to PSG: the right hand side

(RHS) of a rule cannot be shorter than the left hand side

• The rule applications cannot 'shrink' the sentential forms

· For example, our 'goat language grammar' is not

monotonic, because of the rule Begin b b \rightarrow b b

· Sometimes the language with only the empty string is

The Chomsky hierarchy of grammars

Type 2 Context-free grammars

Type 4 Finite (choice) grammars

Type 2.5 Linear grammars

Type 3 Regular grammars

Languages and Grammars

more defintions

- The language that can be derived from a grammar G, is denoted by L(G)
- The notation $\mathfrak{u}\Rightarrow\nu$ is used to denote 'immediate derivation', e.g., $A \Rightarrow aA$
- $\bullet\,$ If a sentential form β can be derived from another sentential form $\boldsymbol{\alpha}$ with zero or more immediate derviations, we write $\alpha \stackrel{*}{\Rightarrow} \beta$
- I β can be derived from α with exactly $\mathfrak n$ immediate derviations, we write $\alpha \stackrel{n}{\Rightarrow} \beta$
- Formaly, $L(G) = \{ w \in \Sigma^* \mid S \stackrel{*}{\Rightarrow} w \}$
- Two grammars G and G' are weakly equivalent if L(G) = L(G')

Ç. Çöltekin, SfS / University of Tübingen

Type 1: monotonic

(LHS)

- As the names says unrestricted, any form of the rewrite
- If a language can be generated at all, it can be defined/generated by a unrestricted PSG
- · No general parsing algorithm exists, and in fact cannot
- The class of languages described by type 0 grammars is called recursively enumerable languages

Ç. Çöltekin, SfS / University of Tübingen

monotonic version

 $S \, \to \, abc$

 $S \, \to \, aSX$ $bXc \, \to \, bbcc$

 $cX \ \to \ Xc$

This also means no ε-rules

allowed as an exception

An example type 1 grammar: anbncn

Winter Semester 2020/21 19 / 35

Type 1: context sensitive

- · A context-sensitive grammar rewrites only one of its
- because of the rule
- ullet a A End ightarrow a ' a
- Parsing is possible with Type 1 grammars, but inefficient
- · In general, not much practical use

Ç. Çöltekin, SfS / University of Tübingen

Ç. Çöltekin, SfS / University of Tübingen

(a)

Type 2: context free

• A context free language requires its LHS to have only a single non-terminal symbol. Rueles are in the form

$$A \,\to\, \alpha$$

(b)

(b)

- This means the rewrite rules cannot be conditioned on context, they are independent of their environment
- Context-free languages have efficient parsers, and used in practical applications
- All programming languages are (subclasses) of context free languages
- Most of natural language parsing is based on context-free parsing (more on this soon)

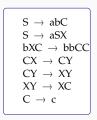

Type 0: unrestricted PSG

- rules are allowed
- exist
- In general, type 0 grammars are not interesting for practical applications

- non-terminal on the LHS.
- · Our 'goat language grammar' is not context-sensitive,
- Context-sensitive and monotonic grammars are equivalent

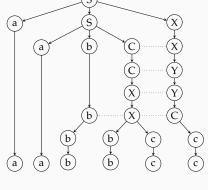

Introduction

An example type 1 grammar: αⁿbⁿcⁿ context-free version

Exercise: try to write a (type 1) grammar for anbmcndm.

Ç. Çöltekin, SfS / University of Tübinger

C. Cöltekin, SfS / University of Tübingen

Winter Semester 2020 / 21 23 / 35

Winter Semester 2020/21 21 / 35

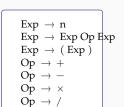

• Regular grammars come in two flavors: right-regular and

• A right-regular grammar allows only two types of rules:

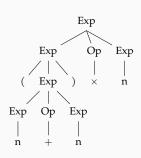

• Right-regular grammars are more common in practical use

• Almost all operations on regular languages are efficient,

Type 2: context free an example

Generating $(n + n) \times n$

Ç. Çöltekin, SfS / University of Tübingen

Winter Semester 2020/21 24 / 35

Type 3: regular

left-regular

 $A \rightarrow a \text{ and } A \rightarrow a B$

 $A \rightarrow a \ \ and \ \ A \rightarrow B \, a$

lots of practical use

· A left-regular grammar allows:

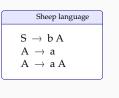

- Generally, $\varepsilon\text{-rules}$ are also allowed A $\,\rightarrow\,\,\varepsilon$

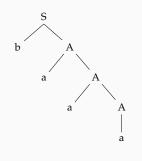

• Regular grammars are equivalent to regular expressions

Type 3: regular

an example (right regular)

Generating 'baaa'

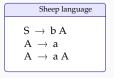

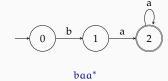

Ç. Çöltekin, SfS / University of Tübingen

Winter Semester 2020/21 26 / 35

Introduction

Regular grammars, regular expressions, and finite-state automata

Ç. Çöltekin, SfS / University of Tübingen

Introduction

Actually enumerating all sentences from a grammar

- · As we sketched it earlier:
 - 1. Start with sentential form 'S'
 - $2. \;\; Pick \, a \; LHS \, that \, maches \, part \, of \, the \, sentential \, form \,$
 - 3. Rewrite the part of the sentential form 4. Repaeat 2 & 3 until either
 - - no non-terminals left in the sentential form: result is a sentence
 - there are no possible productions: dead end
- So far, we picked the rules manually, two strategies to do this automatically:
 - Explore all possible productions simultaneously
 - Ase an 'agenda', and backtrack when we hit a dead end (or generated a sentence successfully)

Type 3: regular an example (right regular) Generating 'baaa' Sheep language $S \,\to\, B\,a$ $B \,\to\, b$ $B \rightarrow B a$

Chomsky hierarhy

a summary and relation to automata

Ç. Çöltekin, SfS / University of Tübingen

Grammar	Language	Automata
Type 0 (unrestricted)	Recursively enumerable	Turing machines
Type 1 (context-sensitive)	Context sensitive	Linear bounded au
Type 2 (context-free)	Context fee	Pushdown automa
Type 3 (regular)	Regular	Finite-state automa

- Other thoretically (or practically) interesting classes exist
- · Our focus in this course will be mainly context-free grammars
- A question: what does it mean for a grammar to be more expressive?

Ç. Çöltekin, SfS / University of Tübingen

Example generation

C. Cöltekin, SfS / University of Tübingen

Note that we need to explore all options type 0 and type 1 grammars.

Cross-serial dependencies

Where do natural language syntax fit?

Jan säit das mer em Hans

Generation and parsing

why unrestricted grammars are undecidible

- The generation procedure we outline can generate all sentence from any PSG
- We can define parsing as waiting until the string we want to parse comes out
- For monotonic/context-sensitive grammars, we can ensure to enumerate shortest strings first
- · For unrestricted grammars, the sentential forms may shrink, as a result
 - if the string comes out, parsing is successful
 - if not, we do not know if it is not in the language, or we haven't obtained it yet

Ç. Çöltekin, SfS / University of Tübingen

The above structure is not possible to parse using context-free languages

· Otherwise, experience so far indicates that a CF-based grammar can describe natural language syntax

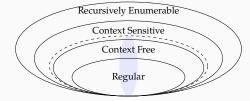

Jan said that we Hans (DAT) the house (ACC) helped paint

es huss

Ç. Çöltekin, SfS / University of Tübingen

hälfed aastriiche

Chomsky hierarchy: the picture

- Chomsky hierarchy of languages form a hierarchy (with some care about empty language)
- It is often claimed that mildly context sensitive grammars (dashed ellipse) are adequate for representing natural languages
- Note, however, not even every regular language is a potential natural language (e.g., a^*bbc^*). The possible natural languages probably cross-cut this hierarchy (shaded region)

Ç. Çöltekin, SfS / University of Tübingen

Winter Semester 2020/21 34 / 35

Summary

- Phrase structure grammars are generative grammars that are finite specifications of (infinite) languages
- They form the basis of theory of parsing
- $\bullet\,$ More expressive grammar classes (type 0 and type 1) are computationally not attractive
- We will look into more practical grammar classes, context-free and regular languages, more closely (next lecture)

Ç. Çöltekin, SfS / University of Tübinger

Winter Semester 2020/21 35 / 35

Example: deriving bbaaa'a

		The grammar
Sentential form	rule	$1.\mathrm{S}\rightarrow\mathrm{Begin}\mathrm{B}\mathrm{A}$
S	(init)	End
Begin B A End	$S \rightarrow Begin B A$ $B \rightarrow b$	2. B → b
Begin b A End Begin b a A End	$A \rightarrow a A$	3. A → a
	$A \rightarrow a A$	4. A → a A
Begin b a a A End Begin b a a a A End	$A \rightarrow a A$ $A \rightarrow a A$	5. a A End \rightarrow a'a
Begin b a a a a End	$A \rightarrow a$	
b b a a a a End	Begin b a \rightarrow b	6. Begin b a \rightarrow b b a
bbaaa'a	a a End → a ' a	7. Begin b b \rightarrow b b

Ç. Çöltekin, SfS / University of Tübinge

C. Cöltekin, SfS / University of Tübinger

Winter Semester 2020/21

Ç. Çöltekin, SfS / University of Tübingen

Example: deriving baa'a

		The grammar
Sentential form	rule	$1. S \rightarrow Begin B A$
S	(init)	End
Begin B A End Begin b A End	$S \rightarrow Begin B A Er B \rightarrow b$	2. B \rightarrow b
Begin b a A End	$A \rightarrow a A$	3. $A \rightarrow a$
Begin b a a A End Begin b a a A End		$4. \ A \ \rightarrow \ a \ A$
Begin b a a ' a	(none)	5. $a A End \rightarrow a'a$
We are stuck with a sentential form with non-terminals.		$6. \ Begin \ b \ a \ \rightarrow \ b \ b \ a$
		7. Begin $b b \rightarrow b b$

 $a^nb^mc^nd^m$ $S\,\to\,X\,Y$ $X \, \to \, aXC$ $X \, \to \, aC$ $Y \, \to \, BYd$ $Y \, \to \, Bd$ $CB \ \to \ BC$ $aB \, \to \, ab$ $bB \ \to \ bb$ $Cd \, \to \, cd$ $Cc \, \to \, cc$
